

## Lecture 9 Curvilinear integral

- Introduction to curvilinear integrals

We suppose given a curve  $\Gamma$  in space  $\mathbb{R}^2$ :  $[0, 1] \ni t \mapsto M(t) = (X(t), Y(t)) \in \mathbb{R}^2$ . The curvilinear abscissa is the length of the curve. We have  $ds = \|dM\| = \sqrt{(X'(t))^2 + (Y'(t))^2} dt$ .

A first example is the arch of parabola. We have in this case  $y = Y(x) = \frac{1}{2} \frac{x^2}{a}$  and we suppose  $0 \leq x \leq a$  with  $a > 0$ . Then  $ds = \sqrt{1 + (Y'(x))^2} dx = \sqrt{1 + (x/a)^2} dx$  in this case.

An arch of circle admits a representation typically given by the relation

$[\theta_{\min}, \theta_{\max}] \ni \theta \mapsto (X(\theta), Y(\theta)) = (R \cos \theta, R \sin \theta)$ . In that case, we have  $ds = R d\theta$ .

We suppose also given a function  $f$  from  $\mathbb{R}^2$  and taking its values in  $\mathbb{R}$ :  $f(M) \in \mathbb{R}$  if  $M \in \mathbb{R}^2$ . The question is to define the curvilinear integral  $I = \int_{\Gamma} f(M) ds$ . This integral depends on the curve  $\Gamma$  and on the function  $f$ . We observe that if  $f(M) \equiv 1$ , then we have  $\int_0^L ds = L$ , the length of the curve  $\Gamma$ .

- Parameterization

If we use the conventional settings  $[0, 1] \ni t \mapsto M(t) = (X(t), Y(t)) \in \mathbb{R}^2$  for defining the curve  $\Gamma$ , the value  $f(M)$  when  $M$  belongs to the curve  $\Gamma$  is equal to  $f(X(t), Y(t))$  and we set  $\int_{\Gamma} f(M(s)) ds = \int_0^1 f(X(t), Y(t)) \frac{ds}{dt} dt$ .

For example, with the previous parabola  $y = \frac{x^2}{2a}$ , we have  $X(x) = x$  and  $Y(x) = \frac{x^2}{2a}$ . Associated with the polynomial function  $f(x, y) = x$ , we obtain the explicitation of the curvilinear integral:  $\int_{\Gamma} f(M(s)) ds = \int_0^a x \sqrt{1 + \frac{x^2}{a^2}} dx$ . After some lines of elementary calculus, this integral is equal to  $\frac{a^2}{3} (2\sqrt{2} - 1)$ .

An other example with the same function  $f(x, y) = x$  and the half circle of radius  $R$  centered at the origin and in the half plane  $\{y > 0\}$ . We have  $\int_{\Gamma} x ds = \int_0^{\pi} R \cos \theta R d\theta = 0$ . With the half circle in the half plane  $\{x > 0\}$ , it comes  $\int_{\Gamma} x ds = \int_{-\pi/2}^{\pi/2} R \cos \theta R d\theta = 2R^2$ .

- The curvilinear integral does not depend on the parameterization

With the choice  $[0, 1] \ni t \mapsto M(t) = (X(t), Y(t)) \in \mathbb{R}^2$  done previously, we have  $I = \int_{\Gamma} f(M(s)) ds = \int_0^1 f(X(t), Y(t)) \frac{ds}{dt} dt$ . If we consider now an other parameterization of the same curve,  $[\alpha, \beta] \ni \theta \mapsto \tilde{M}(\theta) = (\tilde{X}(\theta), \tilde{Y}(\theta)) \in \mathbb{R}^2$ , we have the change of variable  $\theta = K(t)$  such that  $\tilde{M}(\theta) = \tilde{M}(K(t)) = M(t)$ . The associated expression for the curvilinear integral takes the form  $J = \int_{\Gamma} f(M(s)) ds = \int_{\alpha}^{\beta} f(\tilde{X}(\theta), \tilde{Y}(\theta)) \frac{ds}{d\theta} d\theta$ . This expression is coherent

with the previous one: we have  $I = J$ . More precisely, after the change of variable  $\theta = K(t)$  in the integral  $J$ , we have  $J = \int_{\alpha}^{\beta} f(\tilde{X}(\theta), \tilde{Y}(\theta)) \frac{ds}{d\theta} d\theta = \int_0^1 f(X(t), Y(t)) \frac{ds}{d\theta} \frac{d\theta}{dt} dt = I$ .

- Circulation of a vector field

A vector field  $\Phi$  is a vector valued function, defined for  $(x, y) \in \mathbb{R}^2$  by its coordinates. We have  $\Phi(x, y) = (\Phi_x(x, y), \Phi_y(x, y))$ . The circulation  $\gamma$  of the vector field  $\Phi$  along the curve  $\Gamma$  is by definition the curvilinear integral  $\gamma = \int_{\Gamma} (\Phi(M), \tau(M)) ds$  with  $\tau(M) = \frac{dM}{ds}$  is the tangent unitary vector along the curve  $\Gamma$ . Observe that the expression  $(\Phi(M), \tau(M))$  is the scalar product  $\Phi_x \tau_x + \Phi_y \tau_y$ . Then we have also  $\gamma = \int_{\Gamma} (\Phi(M), \tau(M)) ds = \int_{\Gamma} (\Phi_x dX + \Phi_y dY)$  because  $\tau ds = dM = (dX, dY)$ .

For example with the circle  $X(\theta) = R \cos \theta, Y(\theta) = R \sin \theta$ , we have  $\tau(\theta) = (-\sin \theta, \cos \theta)$ . For the circulation  $\gamma = \int_{\Gamma} (\Phi(M), \tau(M)) ds$  of the vector field  $\Phi(x, y) = (-y, x)$  along this circle, we first observe that we have  $(\Phi(M), \tau(M)) = R$ , then  $\gamma = \int_0^{2\pi} R ds = 2\pi R^2$ .

- When the vector field is the gradient of a potential

The vector field  $\Phi$  can be written  $\Phi = \nabla\psi$  for some scalar function  $\psi$  if we have  $\Phi_x = \frac{\partial\psi}{\partial x}$  and  $\Phi_y = \frac{\partial\psi}{\partial y}$ . Then the circulation of this vector field depends only on the extremities of the curve  $\Gamma$ . With  $M(0) = A$  and  $M(1) = B$ , we have  $\gamma = \int_{\Gamma} (\nabla\psi(M), \tau(M)) ds = \psi(B) - \psi(A)$ .

The proof consists to evaluate the scalar product  $(\Phi, dM)$ . We have

$$(\Phi, dM) = \left( \frac{\partial\psi}{\partial x} \frac{dX}{dt} + \frac{\partial\psi}{\partial y} \frac{dY}{dt} \right) dt = \frac{d}{dt} [\psi(X(t), Y(t))] dt. \text{ After integration we obtain}$$

$$\int_A^B (\Phi, dM) = \int_A^B \frac{d}{dt} [\psi(X(t), Y(t))] dt = \psi(B) - \psi(A).$$

- Flux of a vector field in two space dimensions

We recall that for a plane curve, we have chosen in a previous chapter a tangent vector  $\tau = \frac{dM}{ds} = \left( \frac{dx}{ds}, \frac{dy}{ds} \right)$  and a normal vector  $n$  such that  $n_x = \tau_y$  and  $n_y = -\tau_x$ . Then the orthonormal basis  $(n, \tau)$  is a direct basis.

The flux  $\varphi$  of the vector field  $\Phi$  along the curve  $\Gamma$  is defined by  $\varphi = \int_{\Gamma} (\Phi(M), n) ds$  and this curvilinear integral can also be written  $\varphi = \int_{\Gamma} (\Phi_x(M) \tau_y(M) - \Phi_y(M) \tau_x(M)) ds$  or more simply  $\varphi = \int_{\Gamma} (\Phi_x dY - \Phi_y dX)$ .

For example the flux of the field  $\Phi(x, y) = (x, y)$  along the whole circle of radius  $R$  centered at the origin is equal to  $\int_{\Gamma} (\Phi, n) ds = 2\pi R^2$ . The flux of the same vector field along the parabola of equation  $y = \frac{x^2}{2a}$  with the constraint  $0 \leq x \leq a$  is equal to  $\frac{a^2}{6}$ .

## Exercises

- Along an arch of parabola

In the affine Euclidian plane, we consider the parabola of equation  $y = x^2$  and the points  $A(-1, 1)$  and  $B(2, 4)$  on this parabola.

Compute the curvilinear integral  $I = \int_A^B (xy \, dx + (x+y) \, dy)$ . [ $\frac{69}{4}$ ]

- Along an half circle

Let  $\Gamma$  be the half circle in the affine Euclidian plane of radius  $R > 0$ , centered at the origin and included in the half plane  $y > 0$ . Let  $n$  be the unity normal vector pointing in the direction opposite to the origin.

- Illustrate these geometrical data with a drawing.
- How express the curvilinear abscissa  $s$  along the half circle  $\Gamma$ ?
- Compute the curvilinear integral  $I = \int_{\Gamma} x n_x \, ds$ . [ $\frac{1}{2} \pi R^2$ ]
- Compute the curvilinear integral  $J = \int_{\Gamma} [(x-y) \, dx + (x+y) \, dy]$ . [ $\pi R^2$ ]

- Along a complete circle

The letter  $C$  names the circle of radius equal to one centered at the origin. We suppose that it is oriented in the direct sense.

Compute the integral  $I = \int_C [(x-y^3) \, dx + x^3 \, dy]$ . [ $\frac{3}{2} \pi$ ]

- Along an other arch of parabola

Let  $a > 0$  a number and  $[0, a] \ni x \mapsto Y(x) = \frac{1}{2} \frac{x^2}{a}$  an arch  $\Gamma$  of parabola. We introduce the scalar field  $\psi(x, y) = \frac{1}{2} (x^2 + y^2)$  and the vector field  $\Phi = \nabla \psi$ .

- What are the components of the vector field  $\Phi$ ?
- Compute directly the circulation  $\gamma = \int_{\Gamma} (\Phi(M), \tau(M)) \, ds$  of this vector field.
- Using a result proposed in the course, recover this result. [ $\frac{5}{8} a^2$ ]
